Cardiopulmonary Considerations for High School Student-Athletes During the COVID-19 Pandemic: Update to the NFHS-AMSSM Guidance Statement

_Endorsed by the American Medical Society for Sports Medicine (AMSSM) and National Federation of State High School Associations (NFHS)._
Cardiac injury from SARS-CoV-2 infection among hospitalized patients was reported early in the COVID-19 pandemic. Concern and uncertainty regarding the risk of cardiac sequelae in young athletes with SARS-CoV-2 infection led to the development of several consensus recommendations for the cardiac evaluation of athletes following SARS-CoV-2 infection. These guidelines were based on expert opinion and emerging clinical experience but lacked scientific data.

Recent large cohort studies in athletes have demonstrated a low risk of cardiac involvement and have greatly informed the use of cardiac testing after SARS-CoV-2 infection. The Outcome Registry for Cardiac Conditions in Athletes (ORCCA) reported a 0.7% (95% CI: 0.4, 1.1) overall prevalence of cardiac involvement in 3,018 collegiate athletes from 42 universities that had largely undergone cardiac ‘triad’ testing with a resting 12-lead electrocardiogram (ECG), transthoracic echocardiogram (TTE), and troponin blood assay. The ORCCA study also found that athletes with cardiopulmonary symptoms (e.g., chest pain, dyspnea, palpitations) during the acute illness or upon return to exercise were 3.1 (95% CI: 1.2, 7.7) times more likely to have cardiac involvement. Similarly, a study of 789 professional athletes all of whom had undergone cardiac triad testing reported a 0.6% prevalence of cardiac inflammation. Notably, all professional athletes diagnosed with myocarditis or pericarditis also had moderate symptoms defined as fever, flu-like illness, or cardiopulmonary symptoms. Lastly, the Big Ten registry reported a 2.3% prevalence of clinical or subclinical myocardial involvement in 1,597 collegiate athletes who underwent mandatory screening cardiac magnetic resonance imaging (MRI) after SARS-CoV-2 infection. Among the 13 universities participating, the reported prevalence ranged from 0 to 7.6%, with 3 sites reporting no myocardial involvement among 189 athletes. This marked variation is likely not explained by the underlying pathological process but rather by technical and interpretation variability between sites and the relative absence of normative cardiac MRI data in young competitive athletes. Importantly, none of these large cohort studies in collegiate and professional athletes, despite on-going surveillance, have reported an adverse cardiac event associated with SARS-CoV-2 infection.

In light of these studies, an expert task force from the National Federation of State High School Associations (NFHS) and the American Medical Society for Sports Medicine (AMSSM) reconvened to update guidelines for the cardiac assessment of high school student-athletes with prior SARS-CoV-2 infection before sports participation (Figure 1). In the absence of large cohort data in high school athletes, findings in college and professional athletes were extrapolated to the high school level. While many classifications of COVID-19 illness severity...
have emerged, we used the definitions for mild, moderate, and cardiopulmonary symptoms as applied in large athlete cohort studies. Key updates and recommendations include:

- **Asymptomatic and mild symptoms**: Athletes with asymptomatic infections or only mild symptoms (e.g., common cold-like symptoms without fever, gastrointestinal symptoms, or loss of taste/smell) do not require additional cardiac testing unless clinically indicated. Athletes should check-in with a clinician (e.g., physician, nurse practitioner, physician assistant, or athletic trainer) to determine if further clinical evaluation is needed. Athletes should be at least 3-5 days from symptom onset or positive test before beginning an exercise progression.

- **Moderate and cardiopulmonary symptoms**: Additional cardiac testing (e.g., ECG, TTE, troponin) should be considered in athletes with moderate symptoms (e.g., fever >100.4°F, chills, flu-like syndrome for ≥2 days) or initial cardiopulmonary symptoms (e.g., chest pain, dyspnea, palpitations). Athletes with remote infections and moderate symptoms >3 months ago who never received a work-up but have returned to full activity without symptoms do not need additional cardiac testing. Cardiology consultation and cardiac MRI should be considered for abnormal results and as clinically indicated. We recommend athletes are at least 5-7 days from symptom onset and that moderate symptoms are resolved before starting an exercise progression.

- **Cardiopulmonary symptoms on return to exercise**: All athletes with SARS-CoV-2 infections should be closely monitored for new cardiopulmonary symptoms as they return to exercise. Athletes with cardiopulmonary symptoms when they return to exercise (e.g., exertional chest pain, excessive dyspnea, syncope, palpitations, or unexplained exercise intolerance) should undergo additional cardiac testing (e.g., ECG, TTE, troponin) if not already performed and be evaluated by a cardiologist with consideration for a cardiac MRI or other investigations as indicated.

- **Return-to-sport exercise progression**: The return-to-sport progression and timeline should be individualized and is based on numerus factors including baseline fitness, severity and duration of COVID-19 symptoms, and tolerance to progressive levels of exertion. Most athletes will require a graded progression over at least a few days. Absent special indications, a prolonged return-to-sport timeline is not supported by evidence and further restriction from sports participation can contribute to detraining, increased injury risk, and mental health concerns.

- **Preparticipation Physical Evaluation (PPE)**: Additional history questions during a routine PPE should consider if the athlete had a COVID-19 illness. If yes, consider clarifying: when, what symptoms, and if the athlete is experiencing any new symptoms with exercise, especially chest pain.

- **Emergency Action Plan (EAP)**: The task force again stresses the importance of a well-rehearsed EAP for every sport at every venue with clear access to an Automated External Defibrillator (AED).

Update - August 2021
Cardiopulmonary Considerations for High School Student-Athletes during the COVID-19 Pandemic

**Confirmed New Infection**
- Isolate and contact tracing per public health guidelines

**Asymptomatic or Mild illness**
- Check-in with clinician
  - No specific cardiac testing; additional evaluation and cardiac testing based on clinical concern
  - No exercise for at least 3-5 days from symptom onset or positive test; timeline of exercise progression should be individualized

**Moderate illness or Initial Cardiopulmonary Symptoms**
- Medical evaluation and consider ECG, Echo, and Troponin before a return to exercise progression
  - No exercise for at least 5-7 days from symptom onset; moderate symptoms should be resolved before starting an exercise progression

**Cardiopulmonary Symptoms with Return to Exercise**
- Medical evaluation and consider ECG, Echo, and Troponin
  - No exercise until evaluation is complete

**Severe illness or Hospitalization**
- A comprehensive medical evaluation and cardiology consultation is recommended
  - Consider ECG, Echo, and Troponin
  - No exercise until evaluation is complete

- ECG should be compared to previous when available
- Troponin testing (hs-cTnI or cTnI) should be performed after 48 hours without exercise
- Confirmed myocarditis, pulmonary embolism, or other cardiopulmonary disorder should be managed per medical guidelines

**Abnormal testing**

**Return to Play**
- Monitor for new cardiopulmonary symptoms (e.g., chest pain) with exercise*

**Normal testing**

*Cardiopulmonary Symptoms with Return to Exercise (exertional chest pain, excessive dyspnea, unexplained exercise intolerance, palpitations, syncope)
